Alarm Flow

Alarm Flow

Once an event is classified as a Real Alarm, it enters the alarm flow — the structured process that ensures every genuine security threat is received, assigned, and resolved by the right operator at the right time.

1. Alarm Trigger

An alarm is triggered when one of the following occurs:

A camera or sensor detects a real security event that passes Nova 99x AI filtering.

A Health Check failure is detected, such as a camera going offline, obstruction, black screen, or low light condition.

A manual alarm is triggered by an operator or system administrator.

2. Alarm Delivery

Confirmed alarms are delivered to the operator queue in Talos in real time. Each alarm arrives with full context including the customer and site name, device and sensor reference, event timestamp, alarm classification, and a GIF preview or video clip for fast review.

3. Operator Queue

Inside Talos, operators see a live queue of incoming alarms. Each alarm in the queue can be assigned to a specific operator, preventing duplicate handling. The queue displays who is currently working on each alarm, making team coordination visible at a glance.

4. Alarm Review

The operator opens the alarm and reviews the available information:

GIF Preview: A short animated preview of the event for instant context.

Jump Back: Replay the 30 seconds before the alarm was triggered.

Live View: Switch to a live stream of the camera in real time.

Playback: Review recorded footage around the event.

Area Masking: Apply a temporary or permanent mask to a specific zone if needed.

5. Alarm Actions

After reviewing the alarm, the operator takes one of the following actions:

Confirm as Real: Escalate the alarm and trigger the configured workflow — such as calling a technician, sending an SMS or email, or contacting the customer.

Mark as False: Close the alarm as a false positive. This data feeds back into Nova 99x analytics.

Escalate: Assign the alarm to a supervisor or higher-level operator.

6. Workflow Automation

GCXONE integrates with Talos workflows to automate alarm response. Depending on the alarm type and site configuration, workflows can automatically notify the customer, dispatch a technician, send an SMS or email alert, escalate to a supervisor, or log the response for SLA reporting.

7. Alarm Resolution & Audit

Every alarm is closed with a resolution note and stored in the Audit Log with full details including the operator who handled it, the time of action, the steps taken, and the final resolution. This data is available for reporting, SLA validation, and compliance audits.
