Getting to Know Talos

Getting to Know Talos

Evalink Talos is the primary interface where operators handle alarms and managers organize their customer base. This guide walks you through the core navigation and management concepts.

Architecture & Reliability

Talos is built on a cloud-native microservices architecture. Every feature — from alarm processing to site management — runs as an independent service on Amazon Web Services (AWS).

Global Redundancy: Servers are distributed across America, Europe, and Asia.

Fail-Safe Processing: If a specific microservice encounters an issue, the rest of the platform continues to operate without interruption.

Silent Updates: Security patches and feature releases are deployed remotely. When a major change occurs, you will see a prompt to reload the page to apply the update immediately.

Navigating the Dashboard

When you log in, you are greeted with the Main Dashboard providing a high-level overview of your security health.

Alarm Queue: Real-time view of incoming alerts.

My Assigned Alarms: Tracks incidents currently under your review.

What's New: Click your Profile Icon then What's New to see the latest feature releases and security patches.

Understanding Sites in Talos

In Talos, a Site is any entity that can generate an alarm — a building, a specific floor, or even a personal panic button. Each site has one of three statuses:

Active: Fully operational. Alarms are processed and recorded.

Inactive: No alarms are accepted. Inactive sites do not count toward billing.

Test Mode: Used during maintenance. Motion alerts can be ignored while keeping fire alarms active.

Organizing Your Workspace

As your organization grows, use Talos grouping features to keep data structured:

Organizational Units: The highest level of grouping, such as a regional division.

Site Groups: Regional or functional clusters, such as a group of retail locations in a specific area.

Service Companies: Link external technicians or guard services to specific sites for automated task routing.

Creating a Site in Talos

Go to the Sites page and click Create Site.

Choose an ID method — enter a descriptive name manually such as London HQ, or click Sequence to have Talos generate a unique numeric ID automatically. This is useful for large deployments.

Scroll to the Address pane and enter the physical location. Ensure the address matches what is configured in GCXONE for accurate synchronization.

Optionally add custom fields such as License Plate Number or Site Manager Cell to use in automated workflows.

Virtual Devices & Connections

The Virtual Devices tab lists all receivers and connection points in the Talos cloud.

Green Icon: Healthy connection.

Red Icon: Disconnected hardware.

Dual Path (DP): High-security devices using both Ethernet and mobile or cellular backups for redundancy.
