Site Synchronization

Site Synchronization

GCXONE and Talos are designed to work as a unified system. Site Synchronization ensures that all site data created or updated in GCXONE is automatically reflected in Talos, and vice versa — keeping both platforms consistently aligned without manual intervention.

How It Works

By default, GCXONE and Talos synchronize automatically. When a new site is created in GCXONE, it appears directly in Talos. The following data is synchronized between the two platforms:

Site name and address, contact information, geographic coordinates, configuration parameters, and operational status.

Synchronization happens in real time via MQTT messaging, with built-in error handling and retry logic to ensure reliability.

Manual Synchronization

If a specific site is not fully synced, you can force synchronization manually from the site actions menu:

Push to Talos: Sends the latest site data from GCXONE to Talos.

Pull from Talos: Retrieves and updates site data from Talos into GCXONE.

How to Manually Sync a Site

Go to Configuration → Customers and select the relevant customer.

Open the Sites tab and locate the site.

Click the actions menu (⋯) next to the site.

Select Push to Talos or Pull from Talos depending on the direction needed.

Arm & Disarm

From the same actions menu, you can also arm or disarm a site directly without navigating to Talos. This is useful for quick operational control during incidents or maintenance windows.

When to Use Manual Sync

Manual synchronization is needed when a site was recently created but has not yet appeared in Talos, when site details were updated in one platform but not reflected in the other, or when troubleshooting synchronization issues between the two platforms.
