Talos Workflows

Talos Workflows

Workflows are the brain of Talos. They define exactly how an incoming alarm should be handled — whether it's automatically closing a test signal or guiding an operator through a high-priority burglary response.

How Workflow Priority Works

An alarm is always processed for a specific site. Talos searches for a matching workflow in the following priority order:

Site Level: The most specific — workflows configured directly for a single site take highest priority.

Site Group: Workflows applied to a group of sites.

Global/Company Level: The default fallback workflow applied when no site-level or group-level workflow matches.

Creating a Workflow

Step 1 — Define Incoming Conditions: Set the triggers that activate the workflow. This includes the alarm code such as BA for Burglary, the schedule such as After Hours only, and the logic — use All of (AND) for strict matching or One of (OR) for broad categories.

Step 2 — Add Decision Nodes: Ask the system or the operator a question. Examples include automated checks such as whether the site is currently armed, or manual checks such as whether video shows a human presence.

Step 3 — Configure Actions: Define what happens next. Options include sending an automated SMS or email notification, triggering a siren or locking a door, or escalating the alarm to the priority operator queue.

Step 4 — Close and Log: Every workflow must end with a Closing Status such as False Alarm or Police Dispatched. This ensures cleaner reporting and a complete audit trail.

The Operator Alarms Page

The Alarms page is the central cockpit for monitoring staff.

The left side displays all unassigned alarms that have arrived but have not yet been picked up by an operator.

The right side displays columns for each online operator, showing their current active workload and status — Online or Offline.

Bell Icon: Triggers a manual test alarm to verify workflow logic.

Phone Icon: Manually starts a Call Workflow when a customer contacts the monitoring center directly.

Automated vs. Manual Workflows

Use automated workflows for technical signals such as low battery alerts. If the issue does not resolve after a set time, configure the workflow to escalate to a manual workflow for human intervention. This keeps operators focused on situations that genuinely require their attention.
